

Programs	
Client	Client (eg XenCenter)
xapi R	Receiving XCP host
xapi T	Transmitting XCP host
SM	Storage Manager
disk copy	Disk copying utility

Within pool migrate  
Cross-pool migrate  
Storage motion

Phase	Action	Notes
1. Connection	<ol style="list-style-type: none"> <li>1. Client -&gt; xapi R: session.login_with_password(username, password) &lt;- s1</li> <li>2. Client -&gt; xapi R: VM.receive(s1, SR) &lt;- URI list</li> <li>3. Client -&gt; xapi T: session.login_with_password(username, password) &lt;- s2</li> <li>4. Client -&gt; xapi T: VM.migrate(s2, vm, URI list, VDI to SR map)</li> <li>5. xapi T -&gt; xapi R: HTTP HEAD URI (with empty content)</li> </ol>	<p>URIs encode different addresses, protocols (https,http) URIs encode a capability/token</p> <p>Each URI is tried until one successfully returns 200/OK HTTP HEAD run every 30s as heartbeat XenAPI client can cancel either transmitter or receiver</p>
2. Preparation	<ol style="list-style-type: none"> <li>1. xapi T -&gt; xapi R: HTTP PUT URI/metadata (with VM metadata export)</li> <li>2. xapi T -&gt; xapi R: HTTP GET URI/disk/0</li> <li>3. xapi R: SM API VDI.get_url(0) &lt;- iscsi://...../</li> <li>4. xapi T -&gt; xapi R: HTTP GET URI/disk/1</li> <li>5. xapi R: SM API VDI.get_url(1) &lt;- iscsi://...../</li> </ol>	<p>RESTful API = easy to test VM created "hidden" from XenCenter Always 1-1 correspondence between domains and VMs If SRs can't be found, fresh VDIs are created VDIs are attached and registered with iSCSI target</p>
3. Bulk disk transfer	<ol style="list-style-type: none"> <li>1. xapi T: SM API VDI.copy(0, iscsi://...../, new_ref)</li> <li>2. SM spawns a disk copy program</li> <li>3. disk copy: does nothing if both arguments are the same disk</li> <li>4. else disk copy: attaches iSCSI LUN</li> <li>5. else disk copy: switches tapdisks into log-dirty mode</li> <li>6. xapi T: SM API Task.get_state(new_ref)</li> <li>7. xapi T: wait for all VDI.copy Tasks to enter "ready" state</li> </ol>	<p>new_ref allows xapi to query state of the operation</p> <p>copy program sets state to "ready" when it's safe to migrate (i.e. most of the disk has copied)</p>
4. Memory transfer	<ol style="list-style-type: none"> <li>1. xapi T -&gt; xapi R: HTTP PUT URI/memory (with Vmops.suspend data)</li> <li>2. xapi R: SM API VDI.attach</li> <li>3. xapi T waits for domain to finally suspend</li> <li>4. xapi T: SM API VDI.deactivate(0)</li> <li>5. xapi T: wait for all VDI.copy Tasks to enter "finished" state</li> </ol>	<p>VDI.deactivate triggers disk copy to stop iterating</p>
5. Completion	<ol style="list-style-type: none"> <li>1. xapi T -&gt; xapi R: HTTP PUT URI/control (with "done")</li> <li>2. xapi R: resynchronises VM powerstate (Halted, Suspended, Running)</li> <li>3. xapi T: destroy domain</li> <li>3. xapi T: SM API VDI.detach</li> </ol>
